

**Before you let a
model touch your
system of record**

01

Separate read from write

Read access is a privacy question. Write access is a data integrity question. They need different answers and usually different agents.

02

Price a wrong action

A wrongly updated pipeline stage is cheap. A wrongly sent email to a customer is not. Sort the actions by what an error costs, not by how risky they feel.

03

Reversible, or approved first

If you cannot undo it, a human sees it before it happens. There is no third option worth building, and every attempt to find one gets expensive.

04

Give it its own identity

NIST published on exactly this last week. An agent acting on your login makes your audit trail worthless, because everything it did reads as you.

05

Log what changed, not that it ran

Store the before and after. Completed successfully is not a record of anything, and it is the line you will be staring at when something is wrong.

06

Start where being wrong is embarrassing

Not where it is expensive. Contact notes before pricing. Internal summaries before anything a customer reads.

Save this before the beta lands.
